| ref. 1 SPC Protelos rev. 6 7-12-2009 | 0 | afname strontiumklaring met ong. 30% bij patiënten met Clcr 30-70 ml/min | <p>Fase III studies; 85% van de patiënten had Clcr 30-70 ml/min en 6% < 30 ml/min. Clcr was gemiddeld 50 ml/min.</p> <p>Dosisaanpassing niet nodig bij Clcr 30-70 ml/min.</p> <p>Bij Clcr < 30 ml/min wordt gebruik niet aanbevolen, door ontbreken van farmacokinetische gegevens en gegevens over botveiligheid.</p> <p>Scientific discussion: The general safety profile of strontium ranelate in patients Clcr < 30 ml/min was similar to that described in the overall Phase III Safety Set. However the effects of severe renal impairment are known to be potentially deleterious on bone.</p> <p>Discussion of safety data focuses on Phase III data set, which provides long-term information on outcome with the applies/highest tested dose, 2 g/d. Important subsets from Phase III are patients ≥ 80 years (n=1528) and patients with Clcr < 30 ml/min (n=426), as these involve individuals with higher average exposure to Sr and/or higher anticipated degree of frailty.</p> |
