

CYP2D6: citalopram/escitalopram

1998/1999/2000

95% CI = 95% confidence interval, AUC = area under the concentration-time curve, Cl_{or} = oral clearance, C_{ss} = plasma concentration in steady state, CT = citalopram, EM = extensive metaboliser (gene dose 1.5-2.5) (normal CYP2D6 enzyme activity), IM = intermediate metaboliser (gene dose 0.5-1) (reduced CYP2D6 enzyme activity), \ln = natural logarithm, MR = metabolic ratio, NS = non-significant, OR = odds ratio, PM = poor metaboliser (gene dose 0) (absent CYP2D6 enzyme activity), S = significant, $t_{1/2}$ = half-life, UM = ultra-rapid metaboliser (gene dose ≥ 3) (increased CYP2D6 enzyme activity).

Disclaimer: The Pharmacogenetics Working Group of the KNMP formulates the optimal recommendations for each phenotype group based on the available evidence. If this optimal recommendation cannot be followed due to practical restrictions, e.g. therapeutic drug monitoring or a lower dose is not available, the health care professional should consider the next best option.

Brief summary and justification of choices:

Citalopram is primarily metabolised by CYP2C19 and to a lesser extent by CYP3A4. There is insufficient evidence to support a CYP2D6-(es)citalopram interaction (no/no-interactions).

None of the five studies investigating side effects found a significant effect of the CYP2D6 phenotype (Han 2013, Mrazek 2011, Peters 2008, Grasmader 2004 and Sindrup 1993). Of the four studies investigating efficacy, two large studies did not find an effect of the CYP2D6 phenotype (Mrazek 2011 (n = 1235) and Peters 2008 (n = 1953)). In addition, the two small studies contradicted each other. Han 2013 (n = 94) found a decrease in efficacy in patients with reduced CYP2D6 enzyme activity (intermediate metabolisers (IM)) and Tsai 2010 (n = 98) an increase. Both the small size of these studies and the contradictory result, suggest the results of these studies to be chance findings. Only four of the ten kinetic studies found a significant effect of reduced or absent CYP2D6 enzyme activity (intermediate or poor metaboliser (IM or PM)) on the plasma concentration or AUC of (es)citalopram (Chen 2013, de Vos 2011, Fudio 2010 and Herrlin 2003). The effect was small in all four of these studies; an increase by 20-24% for IM and a decrease of S-citalopram by 15% for PM.

You can find a detailed overview of the observed kinetic and clinical consequences per phenotype in the background information text of the gene-drug interactions on the KNMP Kennisbank. You might also have access to this background information text via your pharmacy or physician electronic decision support system.

The table below follows the KNMP definitions for EM, PM, IM and UM. The definitions of EM, PM, IM and UM used in the table below may therefore differ from the definitions used by the authors in the article.

		Significance versus *1/*1 was only determined for Cl _{or} for all patients.					
In pharmacokinetic modelling, only the combination of the CYP2C19 and CYP2D6 genotypes was found to be a significant predictor of Cl _{or} .							
NOTE: Genotyping was for *10. This is the most important gene variant in this Chinese population.							
ref. 2 - escitalopram Han KM et al. CYP2D6 P34S polymorphism and outcomes of escitalopram treatment in Koreans with major depression. Psychiatry Investig 2013;10:286-93. PubMed PMID: 24302953.	3	94 patients with major depressive disorder were treated with escitalopram 5-40 mg/day for 12 weeks. Patients with a score of at least 18 on the 21-item Hamilton Depression Rating scale (HAMD-21) were included. 56 patients completed the study and 38 patients withdrew because of a failure to draw blood, lack of efficacy, personal conflict or other personal decision, loss to treatment, or adverse events. Response was defined as a reduction of 50% or more in the HAMD-21 score. Remission was defined as a HAMD-21 score of 7 points or less. The side-effects profile was assessed using the Udvalg for Kliniske Undersogelser (UKU) Side Effect Rating Scale (UKU-SERS). Other psychotropic drugs, such as antipsychotics and mood stabilizers were excluded, but CYP2D6 inhibitors or inducers were not. Multiple logistic regression analysis with sex and age as covariates was used to investigate the association of *10 with treatment efficacy.					Authors' conclusion: 'Our results suggest that the P allele of the CYP-2D6 P34S polymorphism is a favorable factor in escitalopram treatment for MDD, and that the CYP2D6 P34S polymorphism may be a good genetic marker for predicting escitalopram treatment outcomes.'

PM versus EM: - increase in AUC citalopram from median 4588 to 4700 nM.hour (NS, by 2%) - increase in t _{1/2} from median 30 to 36 hours (NS, by 20%) - increase in AUC desmethylcitalopram from median 1768 to 2400 nM.hour (S, by 36%) - decrease in AUC didesmethylcitalopram from median 370 nM.hour to undetectable (S, by 100%) - no difference in type or frequency of adverse events Citalopram is a weak inhibitor of CYP2D6. NOTE: Genotype unknown.	AUC citalopram versus EM: PM: 98%
ref. 14 - escitalopram SPC Lexapro (escitalopram) 05-09-13.	0 PM: AA	No significant difference in exposure was observed in poor CYP2D6 metabolisers.	
ref. 15 - citalopram SPC Cipramil (citalopram) 01-04-17.	0 PM: AA IM: AA UM: AA	<i>In vivo</i> research has demonstrated that the metabolites of citalopram do not exhibit any clinically relevant polymorphisms of sparteine/debrisoquine oxidation (CYP2D6).	
ref. 16 - escitalopram SPC Lexapro (escitalopram), USA, 04-01-17.	0 PM: AA	Steady state levels of racemic citalopram were not significantly different in poor metabolizers and extensive CYP2D6 metabolizers after multiple-dose administration of citalopram, suggesting that coadministration, with escitalopram, of a drug that inhibits CYP2D6, is unlikely to have clinically significant effects on escitalopram metabolism.	
ref. 17 - citalopram SPC Celexa (citalopram), USA, 04-01-17.	0 PM: AA	Citalopram steady-state levels were not significantly different in poor metabolizers and extensive metabolizers of CYP2D6.	

^a Corrected for dose.

^b Corrected for dose and weight.

NOTE: Phenotyping usually does not distinguish between IM, EM and UM. Therefore, EM in these studies is usually equal to IM+EM+UM.

Comments:

- Escitalopram is the S-enantiomer of citalopram, which is primarily responsible for the antidepressant and anxiolytic effect.

Date of literature search: 11 April 2018.

	Phenotype	Code	Gene-drug interaction	Action	Date
Dutch Pharmacogenetics Working Group decision	PM	4 A	No	No	14 May 2018
	IM	4 C	No	No	
	UM	4 AA	No	No	

Mechanism:

Citalopram is primarily metabolised by CYP2C19 and to a lesser extent by CYP3A4 to N-desmethyleitalopram. N-desmethyleitalopram is converted to didesmethylcitalopram by CYP2D6.

Although desmethyleitalopram has antidepressant activity, the activity is low and clinically non-significant at standard doses (Herrlin, 2003).
